PHARMACEUTICALLY ACTIVE AMINESBACKGROUND OF THE INVENTION1. Field of the Invention

Disclosed are aromatic, alkyl, bicyclic and cycloalkyl amines.  
5 These compounds are useful pharmaceutical agents in treating head injury, spinal cord trauma, stroke and a number of other related injuries and conditions.

2. Description of the Related Art

The non-amine portion of some of the aromatic amines (I) are  
10 known.

The non-amine portions of the alkyl amines (II) are known to those skilled in the art or can readily be prepared from known compounds by methods known to those skilled in the art.

The non-amine portions of the bicyclic amines (III) are known to  
15 those skilled in the art. See, in particular, US Patents 3,947,473, 4,003,919, 4,018,799, 4,026,907 and 4,681,890. See also British Patent 947,885 and Chem. Abst., 60, 11991 (1964). EP 202,580-A discloses 3,4-dihydrobenzopyran derivatives, similar to the non-amine portion of the bicyclic amines (III), which are attached to a 4-phenylmethyl-1-piperazinyl or a 4-(4-pyridinylmethyl)-1-piperazinyl  
20 group. While these compounds are similar to the bicyclic amines (III) of the present invention, the bicyclic amines (III) do not have a methylene group between the phenyl or 4-pyridinyl substituent and the piperazinyl group.

25 The non-amine portions of the cycloalkyl amines (IV) are known to those skilled in the art or can readily be prepared from known compounds by methods known to those skilled in the art.

The non-amine portions of the aromatic bicyclic amines (V) are known to those skilled in the art. See, in particular, US Patents  
30 4,181,665 (isochromans - 6 member heterocyclic ring) and 4,153,612 (2-benzoxepins - 7 member heterocyclic ring). These patents also disclose the non-amine portion of the aromatic bicyclic amines (V), attached to various amines, but different amines than included within the present invention. Those amines were disclosed as possessing  
35 antihypertensive and tranquilization activity including antidepressant and antianxiety effects. The activity of the aromatic bicyclic amines (V) is quite different.

Published PCT patent application serial No US 86/01797, Interna-

-2-

tional Disclosure Number WO87/01706 (PCT 86/01797) discloses amino steroids where the amine portion includes acyclic, aromatic and heterocyclic amine functionality very similar to the amino substituents, where M is  $-NR_A R_B$ , of the present invention. In PCT 86/01797, the amino substituent was attached to the terminal carbon atom of the C<sub>17</sub> side chain of a steroid. The present invention differs from PCT 86/01797 in that the non-amine portion is not a steroid. PCT 86/01797 also disclosed numerous references involving various amines and amino substituents which are incorporated here by reference. PCT 86/01797 is the reference which discloses amino substituents most similar to those of the present invention.

The non-amine portion of the hydroquinones (VI) and quinones (VII) are well known to those skilled in the art. Great Britain patent 2,127,814A discloses amino-quinones containing a fused ring containing a nitrogen atom, the hydroquinones (VI) and quinones (VII) of the present patent do not contain a ring fused to the hydroquinone or quinone. J6 1,254,546A discloses acyclic amine quinone derivatives which contain only a simple nitrogen atom in a long side chain of carbon atoms. US Patent discloses amino-quinones but of an indole type.

The non-amine portion of the amino ethers (VIII) are known to those skilled in the art. JA-7,124,369 discloses heptatrienes which are not similar to the bicyclic aromatic/7-member nitrogen-oxygen containing ring system of the amino ethers (VIII)

The non-amine portion of the bicyclic amino ethers (IX) are known to those skilled in the art. EP 244018-A discloses oxazole-amine derivatives but where the oxazole ring is not fused to a phenyl ring as in the present situation. EP 199400-A discloses a fused oxazole-phenyl ring system having a side chain containing nitrogen.

EP 202,580-A discloses 3,4-dihydrobenzopyran derivatives almost identical with the compounds encompassed by formula (XI). The utility of the compounds disclosed in EP 202,580-A is as a prophylactic for gastritis caused by inflammation of the gastric mucosa. The utility claimed for these agents in the present patent application has nothing to do with gastritis caused by inflammation of the gastric mucosa.

#### DETAILED DESCRIPTION OF THE INVENTION

The aromatic amines (I) are produced by condensing the amine

-21-

corresponding to the desired aromatic amine (I) with the non-amine portion corresponding to the desired aromatic amine (I). With regard to the non-amine portion, when  $R_1$  and  $R_2$  are not -H, and  $R_3$  is -OH,  $C_1$ - $C_3$  alkoxy or -O-CO-( $C_1$ - $C_4$  alkyl) the non-amine portion is produced by starting with the desired aromatic ring as the phenol and alkylating it with the appropriate unsaturated halide, such as allyl bromide (for  $n_1 = 2$ ) to form the unsaturated phenolic ether. This compound is then rearranged to give the unsaturated group para to the  $R_3$  group by the procedure of Tarbell & Kincaid see, J. Am. Chem. Soc., 62, 728 (1940). The terminal unsaturated group is then transformed to the alcohol by known methods, which is then converted to a good leaving group such as chloride, bromide, iodide, mesylate, tosylate, etc and this compound is then condensed with the appropriate amine by the procedures disclosed in PCT 86/01797. Suitable solvents include acetonitrile, THF and DMF; acetonitrile is preferred. Suitable bases include carbonate, bicarbonate and TEA; preferred is carbonate. While not necessary, it is preferred, to add a catalytic amount of iodide ion when reacting the non-amine and amine portion to produce the desired aromatic amine (I). When  $R_3$  is -H, it is preferred to start with the appropriate substituted benzoic acid or benzaldehyde derivative. Here again the side chain is built up to the desired length, a good leaving group added and then condensed with the appropriate amine. The compounds where  $X_1$  is -CH<sub>2</sub>- and  $n_1$  is 0 are prepared by reducing Ar-CHO or Ar-COOH (Ar refers to  $\phi$  with the appropriate variable substituents as defined in the claims for the aromatic amines (I)) with lithium aluminum hydride to Ar-CH<sub>2</sub>-OH. The mesylate or tosylate of the alcohol is prepared in the usual way (using mesyl or tosyl chloride and triethylamine in methylene chloride) and it is then reacted with the appropriate amine (except A-55 which is generated in situ, this exception will be understood to apply in all cases) to yield the desired product. Alternatively, one can react Ar-H and chloromethylate with paraformaldehyde and concentrated hydrochloric acid. This reaction works best if the aromatic ring is activated by one or more alkoxy groups. The product, Ar-CH<sub>2</sub>Cl, is then reacted with the appropriate amine. When  $X_1$  is -CH<sub>2</sub>- and  $n_1$  is 1, the above procedure can be followed starting with the corresponding Ar-CH<sub>2</sub>-CHO or Ar-CH<sub>2</sub>-COOH. Alternatively, one can begin with a phenol which is unsubstituted at either the ortho or

-22-

para positions. The allyl ether is prepared in the usual way from allyl chloride and the phenol. Next the allyl ether is thermally rearranged in a Claisen Rearrangement. If the phenol is substituted at C-2 and C-6 positions, the rearrangement will give a 4-CH<sub>2</sub>CH=CH<sub>2</sub> substituent. This can be cleaved by ozone and reduced to the 4-CH<sub>2</sub>CH<sub>2</sub>OH group. The chloride/bromide/iodide/mesylate/tosylate is prepared from this alcohol in the usual way and reacted with the appropriate amine. Where X<sub>1</sub> is -CH<sub>2</sub>- and n<sub>1</sub> is 2, the above method produces a phenol having a -CH<sub>2</sub>CH=CH<sub>2</sub> group. This olefin is reacted with diborane in the usual way to form the organoborane which is then oxidized with hydrogen peroxide and base to the terminal alcohol-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH. The leaving group and reaction with the appropriate amine are performed in the usual manner. Alternatively, one can begin with a Ar-CHO, which is reacted with malonic acid and a weak base to form Ar-CH=CHCOOH which can be hydrogenated and reduced with lithium aluminum hydride to Ar-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH [J. Med. Chem., 751, (1980)] which can be converted in the usual way to the aromatic amine (I). When X<sub>1</sub> is -CH<sub>2</sub>- and n<sub>1</sub> is 3, it is preferred to begin with a substituted anisole which is unsubstituted at C-2 or C-4. This is reacted with succinic anhydride and aluminum chloride in benzene or toluene. The product, Ar-COCH<sub>2</sub>CH<sub>2</sub>COOH, is reduced with diborane in THF, followed sometimes by hydrogenation over Palladium on carbon in acetic acid, to the desired Ar-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH which is converted to the aromatic amine (I). When X<sub>1</sub> is -CH<sub>2</sub>- and n<sub>1</sub> is 4, 5 or 6, it is preferred to first prepare a Grignard reagent from Ar-Br. The Grignard reagent is reacted with the appropriate 5-7 membered cyclic ketone. The alcohol product is oxidized and cleaved to the keto-acid which is reduced with boron hydride to the alcohol Ar-(CH<sub>2</sub>)<sub>4-6</sub>CH<sub>2</sub>OH which is converted to the aromatic amine in the usual way.

The aromatic amines (I) where X<sub>1</sub> is -CR(CH<sub>3</sub>)- and n<sub>1</sub> is 1 are prepared by reacting the amine M with a haloketone such as chloroacetone. The adduct, CH<sub>3</sub>COCH<sub>2</sub>-M, is reacted with a Grignard such as Ar-MgBr. The product has the above structure when R is -OH. The alcohol can be acetylated and reduced to give R = -H. The aromatic amines (I) where X<sub>1</sub> is -O- are prepared by beginning with the corresponding phenol. This is reacted with the dibromide Br(CH<sub>2</sub>)<sub>n1</sub>-Br (or the corresponding dichloride) where n<sub>1</sub> is 4, 5, 6 in the presence of hydroxide and in an alcoholic solvent such as ethanol. The

-23-

product,  $\text{Ar-O-(CH}_2\text{)}_{n1}\text{-Br}$ , is reacted with the amine M in a solvent such as acetonitrile in the presence of a base such as carbonate to yield the desired product. Alternatively, starting with the same phenol, it is reacted with chloroethanol in an alcoholic solvent in the presence of hydroxide to give  $\text{Ar-O-CH}_2\text{CH}_2\text{OH}$ , which is converted to the aromatic amine (I) in the usual manner. For aromatic amines (I) where  $X_1$  is  $\text{-CO-}$  it is preferred to start with the known compounds where  $\text{Ar-CO-(CH}_2\text{)}_{n1}\text{-halogen}$ . The halide is then reacted with the appropriate amine in the usual manner to produce the aromatic amine (I). Where  $X_1$  is  $\text{-CH(OH)-}$ , one starts with product above ( $X_1$  is  $\text{-CO-}$ ) and reduces it with a reducing agent such as sodium borohydride in ethanol. For the aromatic amines (I) where  $X_1$  is  $\text{-C(OH)(R}_{13}\text{)-}$  where  $R_{13}$  is  $\text{C}_1\text{-C}_3$  alkyl or phenyl (optionally substituted) these compounds are prepared by reaction of the compounds where  $X_1$  is  $\text{-CO-}$  with the appropriate Grignard reagent ( $\text{R}_{13}\text{-Mg-X}$ ). For the aromatic amines (I), where  $X_1$  is  $\text{-N(R}_4\text{)-}$ , known anilines are the starting materials. The corresponding amides are formed by reaction of the aniline with an acid chloride ( $\text{R}_4\text{-COCl}$ ) or anhydride  $\text{R}_4\text{-CO}_2\text{C-R}_4$  in the presence of a base such as triethylamine in a solvent such as methylene chloride. The resulting amides are reduced with lithium aluminum hydride to  $\text{Ar-NH(R}_4\text{)}$ . These compounds are reacted with the dibromide  $\text{Br(CH}_2\text{)}_{n1}\text{Br}$  or analogous dichloride or diiodide where  $n = 4, 5, 6$  in the presence of hydroxide and in an alcoholic solvent such as ethanol. The product,  $\text{Ar-N(R}_4\text{)(CH}_2\text{)}_{n1}\text{Br}$ , is reacted with the amine, M, in acetonitrile in the presence of carbonate to give the aromatic amine (I).

For the aromatic amines (I) where  $n_{13}$  is 1,  $\text{Ar-X}_1\text{-C}_{n1}(\text{R}_8)(\text{R}_9)\text{-O-(CH}_2\text{)}_{n14}$ , where  $x_1$  is not  $\text{-NH-CO-}$  or  $\text{-NR}_4\text{-}$  and  $n_1$  is 2 or more it is preferred to begin with the compound  $\text{Ar-X}_1\text{-C}_{n1}(\text{R}_8)(\text{R}_9)\text{-OH}$  and convert it to the halide, mesylate or tosylate in the usual way. This is reacted with  $\text{HO-(CH}_2\text{)}_{n14}\text{-O-Protecting group}$  where the protecting group is tetrahydropyranyl or trimethylsilyl in the presence of a base such as sodium hydride or potassium t-butoxide. Next the protecting group is removed to give  $\text{Ar-X}_1\text{-C}_{n1}(\text{R}_8)(\text{R}_9)\text{-O-(CH}_2\text{)}_{n14}\text{-OH}$ . The terminal alcohol is converted to the mesylate, tosylate, halide and reacted with the appropriate amine in the usual way to obtain the desired product.

With regard to isolation, the compounds are generally isolated

by extraction between sodium bicarbonate and methylene chloride. The organic phase is washed and dried in the usual manner and concentrated. When necessary, the products are purified by silica gel chromatography eluting with either methanol and methylene chloride or ethyl acetate and hexane.

The alkyl amines (II) are produced by condensing the amine corresponding to the desired alkyl amine (II) with the non-amine portion corresponding to the desired alkyl amine (II) by the procedures disclosed in PCT 86/01797. The non-amine portion should have a good leaving group such as mesylate, tosylate, -Br, etc. While not necessary it is preferred to add a catalytic amount of iodide ion, see EXAMPLE 1. In the case of certain 3,6-bis(2-pyridinyl)pyridazines (A-55) the amine is not preformed and then attached to the non-amine portion; the amine is formed in situ, see EXAMPLE 17.

The bicyclic amines (III) are prepared from the corresponding amine and bicyclic portions by means well known to those skilled in the art. The bicyclic portions where the terminal group is -COOH are known or can readily be produced from known compounds, see US Patents 3,947,473, 4,003,919, 4,018,799, 4,026,907 and 4,681,890. The acid can be activated with an agent such as 1,1'-carbonyldiimidazole or 1,3-dicyclohexylcarbodiimide in a solvent such as THF, ether or methylene chloride following which it is contacted with the desired amine to form the desired bicyclic amine where  $X_3$  is -CO-. Alternatively, the related acid chlorides can be used to react with the desired amine, see EXAMPLE 68. In the cases where  $X_3$  is  $-(CH_2)_3-$ , the methylene compounds are formed by first forming the amide as above then reducing it with a reducing agent such as lithium aluminum hydride or borane dimethylsulfide. Alternatively, though less preferably, the -COOH group can be reduced to the corresponding  $-CH_2-OH$  which can then be transformed to a good leaving group such as mesylate, tosylate or bromide and then reacted with the desired amine to form the desired corresponding bicyclic amine (III). In the case where  $X_3$  is -CO-O-, the phenol acetate (or other ester) of 6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid is activated with oxalyl chloride in a solvent such as acetonitrile, see Helv. Chim. Acta 61, 1675 (1978). A solution of the requisite aminoalcohol in pyridine or pyridine/acetonitrile is added. The reaction mixture is allowed to stand several hours at 20-25°, followed by workup. The reaction

mixture is partitioned between methylene chloride and aqueous sodium bicarbonate. The phases are separated, the organic phase is dried, concentrated, chromatographed, if needed, over silica gel to give the bicyclic amine (III) where  $X_3$  is  $-CO-O-$ . See EXAMPLES 161 and 162.

5        A general procedure for synthesis of the amide type ( $X_3$  is  $-CO-$ ) bicyclic amines (III) is as follows. 1,1'-Carbonyldiimidazole (1.1 equivalents) is added to a stirred solution of non-amine portion of the starting material (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) about 4-8 mmol in THF (10-12 ml). The mixture is  
10       stirred at 20-25° for 30-60 min. and the appropriate amine (1.0-1.1 equivalents) in THF or methylene chloride (10-20 ml) is added dropwise and the mixture stirred at 20-25° for 4-18 hr (monitored by TLC). When the reaction is complete the mixture is concentrated under reduced pressure and partitioned between ether (100-150 ml) and water  
15       (100-150 ml). The ether phase is washed with water, saline, dried over sodium sulfate and the solvent removed under reduced pressure. If purification is necessary, column chromatography is performed as needed on silica gel. In some cases the products containing basic nitrogen atoms are converted to acid addition salts.

20       A general procedure for reduction of the amide type ( $X_3$  is  $-CO-$ ) to the reduced type ( $X_3$  is  $-CH_2-$ ) of bicyclic amine (III) is as follows. To a stirred suspension of lithium aluminum hydride (LAH, 4 molar equivalents) in dry THF (20-25 ml), maintained at 0-50° depending on the nature of the particular compound, is added dropwise  
25       over 10-15 min a solution of the appropriate amide (4-8 mmol) in dry THF (25-50 ml). The mixture is stirred at the appropriate temperature for 30 -120 min and then cooled in an ice-water bath. To the reaction mixture is carefully added dropwise water (1 ml/g of LAH), followed by aqueous sodium hydroxide (15%, 1 ml/g of LAH) and finally water (3  
30       ml/g of LAH). The mixture is stirred for 30 min and filtered through celite. The filtered solids are washed with ether (50-100 ml, 2 times). The combined washes and filtrate were extracted with aqueous hydrogen chloride (10%, 50-75 ml, 2 times). The pH of the combined acidic extracts is raised to approximately 12 with aqueous sodium  
35       hydroxide (50%) with ice bath cooling and the basic mixture is extracted with chloroform (50-100 ml, 2 times). The combined chloroform extracts are dried over sodium sulfate, the solvent removed at reduced pressure and the crude product flash chromatographed on

-26-

silica gel. In some cases the products were converted to acid addition salts.

The cycloalkyl amines (IV) are prepared by methods well known to those skilled in the art. It is preferred to start with a 3-alkoxycyclopent-2-en-1-one, 3-alkoxycyclohex-2-en-1-one or 3-alkoxycyclohept-2-en-1-one depending on whether  $n_5$  is 1, 2 or 3. It is preferred that the alkoxy group be ethoxy. Grignard reaction with  $X-Mg-(CH_2)_{n_4}-O$ -magnesium to the  $\alpha,\beta$ -unsaturated ketone followed by acid hydrolysis gives the desired 3-substituted cycloalkyl-2-en-1-one. The terminal hydroxyl group is then oxidized with an oxidizing agent such as pyridinium dichromate to the corresponding aldehyde which is then contacted with the amine corresponding to the amino portion of the desired cycloalkyl amine (IV). It is preferred to contact the amine with the non-amine portion in the presence of sodium cyanoborohydride. When  $n_4$  is 3 it is preferred to use  $X-Mg-(CH_2)_2-C^*(H)-O-(CH_2)_2-O^*$  [where the atoms marked with an asterisk (\*) are bonded to each other resulting in the formation of a ring] as the Grignard reagent.

The non-amine portions of the aromatic bicyclic amines (V) are known to those skilled in the art. See, in particular, US Patents 4,181,665 and 4,153,612. The aromatic bicyclic amines (V) of the present invention are made by the same method as the amines of US Patents 4,181,665 and 4,153,612.

The hydroquinones (VI) and quinones (VII) are readily interchangeable as is well known to those skilled in the art. It is realized that with the hydroquinones (VI) when  $R_{27}$  and  $R_{28}$  are other than -H, that these groups are lost in the conversion to the corresponding quinone (VII). A hydroquinone (VI) and its corresponding quinone (VII) are both useful in the same manner and same way and therefore when the term hydroquinone (VI) is used it means and includes the corresponding quinone (VII) for purposes of this patent.

The hydroquinones (VI) are prepared by reaction of the aldehyde group of the non-amine portion of the hydroquinone starting material with the desired amine. The reaction is performed in the presence of an agent such as sodium cyanoborohydride in a polar solvent such as methanol or acetonitrile at about 20-25°, preferred is methanol. Several of the non-amine starting materials are known, see for example, Hel. Chem. Acta 46, 650 (1963) and Chem. Pharm. Bull. 30,

-27-

2797 (1982). Starting materials with the desired chain length are synthesized by known chemical reactions. The free hydroquinone or hydroxyprotected non-amine portion of the hydroquinone (VI) can be used. In the later case, the hydroxy-protecting groups, usually  
5 esters such as acetate or ethers such as t-butyldimethylsilyl, are removed by means well known to those skilled in the art, for example, hydroxide/water/acetone followed by acidification or tetra-N-butyl ammonium chloride. The hydroquinones (VI) can readily be transformed  
10 into the corresponding quinones (VII) by means known to those skilled in the art, for example ferric chloride/ethyl acetate. Alternatively, using means known to those skilled in the art, one can start with the non-amine portion of a quinone, see Chem. Pharm. Bull. 30, 2797 (1982), transform it to the corresponding hydroquinone, and react it with the appropriate amine to produce the desired hydroquinone (VI).

15 The amino ethers (VIII) are prepared by contacting the hydroxyl protected (or unprotected) aldehyde group of the non-amine portion of the amino ether (VIII) with the desired amine in the presence of a reducing agent such as sodium cyanoborohydride in a polar solvent such as methanol. Alternatively the appropriate aldehyde and amine  
20 can be contacted in a non-polar solvent such as toluene at about 50-116° and removing the solvent. The resultant imine can then be contacted with a reducing agent such as sodium borohydride in a polar solvent such as methanol. The non-amine portion of the amino ether (VIII) starting materials are known to those skilled in the art, see  
25 for example, Hel. Chem. Acta 46, 650 (1963) and Chem. Pharm. Bull. 30, 2797 (1982). If present the hydroxy protecting groups can be removed at this time. The hydroquinone-amine intermediate is then reacted with an agent such as chloroacetylchloride in the presence of a base, such as pyridine or triethylamine at about 0-30° in a solvent  
30 such as ether to provide the appropriate chloroacetamide. Final cyclization can be effected by treatment of the acetamide with base, such as potassium carbonate, in a polar solvent, such as acetone at about 0-50°. If desired the cyclic amide can be reduced with a reducing agent such as lithium aluminum hydride in an aprotic solvent  
35 such as ether to the corresponding amine. The protected hydroquinones can be prepared by standard methods, see for example J. Am. Chem. Soc. 94, 6190 (1972) from known hydroquinone carboxaldehydes.

The amino ethers (IX) are of two types, ones with the nitrogen.

atom "up" (IXA) and with the nitrogen atom "down" (IXB). The amino ethers (IXB) are prepared by reacting the appropriate 4-aminoresorcinol with chloracetyl chloride (or an equivalent reagent) in the presence of a base, such as pyridine or triethylamine at 0-30° in an aprotic solvent such as ether. The resorcinol starting materials are known to those skilled in the art or can readily be prepared from known compounds by known methods. Cyclization is effected by treatment with a base such as potassium or sodium carbonate in a polar solvent such as acetone. Alkylation of the sodium or potassium salt of the cyclic amide (hydroxy protected) with the appropriate reagent, R<sub>A</sub>-leaving group where leaving group is -Br, Cl or -O-tosyl at about -78° to about 25° in a solvent such as ether, provides the amide product. The amide can be reduced, if desired, by reaction with a reducing agent such as lithium aluminum hydride or borane at about 0-50° to provide the cyclic amine. Alternatively, the cyclic amide can be reduced with lithium aluminum hydride or borane and the cyclic amine reacted with R<sub>A</sub>-leaving group or with R<sub>A</sub>-CHO in the presence of a base such as potassium carbonate or sodium cyanoborohydride respectively. The amino ethers (IXA) are prepared in a similar manner. The starting materials are known, see Synthesis 69 (1982) and Can. J. Chem. 44, 1874 (1966).

Prodrugs of the aromatic amines (I), bicyclic amines (III), hydroquinones (VI), amino ether amines (VIII) and bicyclic amino ether amines (IX) are prepared in general by reacting the phenol or salt of the phenol with the appropriate prodrug substituent such as carboxylic acid, isocyanate, anhydride, etc. More specifically, for the prodrug -PO<sub>2</sub>-O- the phenol is reacted with phosphorous oxychloride and this intermediate compound is then reacted with water. For -CO-(CH<sub>2</sub>)<sub>n</sub>-R<sub>51</sub> where R<sub>51</sub> is -N(alkyl)<sub>2</sub>, and -CO-C\*-CH=CH=C(-NR<sub>52</sub>)-CH=CH\* (where R<sub>52</sub> is -H or C<sub>1</sub>-C<sub>3</sub> alkyl and where the atoms marked with an asterisk (\*) are bonded to each other resulting in the formation of a ring), the prodrugs are prepared from the phenol and the carboxylic acid in the presence of 1,3-dicyclohexylcarbodiimide in a polar aprotic solvent such as methylene chloride. When R<sub>51</sub> is -NH<sub>2</sub>, the t-butyl carbamate of the prodrug is prepared as above, followed by cleavage of the carbamate by reaction with an acid such as hydrochloric acid in methanol or trifluoroacetic acid about 0-25°. The compounds with the prodrug of the formula -O-CH<sub>2</sub>-O-CO-

(CH<sub>2</sub>)<sub>n21</sub>-NR<sub>51-1</sub>R<sub>51-2</sub> are prepared by reaction of the salt of the phenol with the appropriate chloromethyl ether in a solvent such as tetrahydrofuran. The chloromethyl ethers can be prepared by the procedure of J. Org. Chem. 48, 5280 (1983). Prodrugs of -CO-CH=CH-CO-O<sup>-</sup> or -CO-(CH<sub>2</sub>)<sub>n21</sub>-COO<sup>-</sup> are prepared by reaction of the (sodium) salt of the phenol with the anhydride at about 0-60°. Alternatively, the phenol may be coupled with the diacid utilizing 1,3-dicyclohexylcarbodiimide and the resulting acid exposed to a base such as sodium carbonate to form the desired salt. Other prodrugs are prepared by known procedures.

The aromatic amines (I), alkyl amines (II), bicyclic amines (III), cycloalkyl amines (IV), aromatic bicyclic amines (V), hydroquinone amines (VI), quinone amines (VII), amino ether amines (VIII) and bicyclic amino ether amines (IX) collectively are referred to as amines (X), of the present invention are reacted with acids to form amine salts by methods known to those skilled in the art and the resulting salts are more water soluble and therefore preferable to use when an aqueous formulation is desired such as a solution for IV use. Generally the amines (X) possess one or more basic nitrogen atoms. Because of this they can be converted to an acid addition pharmaceutically acceptable salt. The pharmaceutically acceptable salt forms of the amines (X) are generally preferred over the free base form since the salts have greater water solubility and form crystals more suitable for pharmaceutical purposes. An acid addition salt of the amines (X) can be converted to the free base, which can be converted to any desired pharmaceutically acceptable acid addition salt by methods known to those skilled in the art. It is preferred that the acid addition salt be prepared by reacting the free base of the amines (X) with an approximately stoichiometric amount of an acid, such as hydrochloric, hydrobromic, hydroiodic, sulfuric, phosphoric, acetic, lactic, citric, succinic, benzoic, salicylic, pamoic, cyclohexanesulfamic, methanesulfonic, naphthalenesulfonic, p-toluenesulfonic, maleic, fumaric, oxalic acid and the like. It is preferred that the acid be selected from the group consisting of hydrochloric, maleic, methanesulfonic and fumaric acids.

The amines (X) and acid addition salts thereof can be isolated as hydrates or solvates, and such forms are regarded as equivalent to the corresponding amines (X) not containing water or solvent.

-30-

It is preferred that the amine (X) be an aromatic amine (I), alkyl amine (II) or bicyclic amine (III). It is more preferred that the amine (X) be an aromatic amine (I) or bicyclic amine (III). It is preferred that the amine portion be a 1-piperazine substituted in the 4- position with  $-(CH_2)_j$ -heteroaryl where j is preferably 0 and heteroaryl is preferably (a) pyrimidin-4-yl substituted in the 2- and/or 6- position with 4-morpholinyl, 1-pyrrolidinyl or (b) pyridinyl substituted in the 3- position with  $-NR_m-3R_M-3$ . It is more preferred that the amine be A-22 (PREPARATION A-22) or A-47 (PREPARATION A-47).

With the aromatic amines (I), it is preferred that  $X_1$  be -O-,  $-CH_2-$  or  $-CO-$ . It is preferred that  $n_1$  be 0-6, it is more preferred that  $n_1$  be 1-6. It is preferred that  $R_3$  be -OH or  $C_1-C_3$  alkoxy. It is preferred that  $R_8$  and  $R_9$  be -H. It is preferred that  $R_{22}$  and  $R_{23}$  are -H. It is preferred that  $R_1$  and  $R_2$  are the same and are -H,  $-CH_3$  or t-butyl.

With the alkyl amines (II) it is preferred that  $n_2$  is 4-8, more preferably 6. It is preferred that  $X_2$  be -H, -OH,  $-O-CO-(C_1-C_4)$  or  $-O-CO-aryl$ .

For the bicyclic amines (III) it is preferred that  $R_{16-1}$  or  $R_{16-2}$  is  $-CH_3$ . It is preferred that  $R_7$  is -H. It is also preferred that  $R_{10}$ ,  $R_{11}$  and  $R_{12}$  are all  $-CH_3$ . It is preferred that  $n_6$  is 1. It is preferred that  $X_3$  is  $-CO-$  or  $-CH_2-$  and that  $W_2$  is -O-.

For the cycloalkyl amines (IV) it is preferred that  $n_4$  is 3-6 and  $n_5$  is 2.

With the aromatic bicyclic amines (V) it is preferred that  $R_{17}$  is  $-(CH_2)_{n_9}-W_1$ .

The amines (X) of the present invention are useful pharmaceutical agents in treating a number of different medical conditions in humans and useful warm blooded animals. The 3,4-dihydrobenzopyran compounds (XI) are known, see EP 202,580-A. These compounds are used in the same way for the same purposes as the amines (X) of the present invention.

In humans, the amines (X) of the present invention are useful in treating spinal trauma, mild and/or moderate to severe head injury, subarachnoid hemorrhage and subsequent cerebral vasospasm, ischemic (thromboembolic) stroke, excess mucous secretion, asthma, muscular dystrophy, adriamycin-induced cardiac toxicity, Parkinsonism,

-31-

Alzheimer's disease, other degenerative neurological disorders, multiple sclerosis, organ damage during reperfusion after transplant, skin graft rejection, hemorrhagic, traumatic and septic shock, and conditions such as severe burns, ARDS, inflammatory diseases such as osteo- or rheumatoid arthritis, nephrotic syndrome (immunological),  
5 systemic lupus erythematosus, allergic reactions, atherosclerosis, inflammation (for example dermatological, inflammatory and psoriasis conditions), emphysema, stress induced ulcers, cluster headaches, complications from brain tumors (e.g. peritumoral edema), radiation  
10 damage (for example during radiation treatment or from accidental exposure to radiation), damage after MI, pre-birth infant strangulation and infant hypoxia syndrome, such opthalmic disorders as uveitis and optic neuritis, and malignant hyperthermia.

In humans, the amines (X) are useful in preventing damage  
15 following cardiopulmonary resuscitation, neurological or cardiovascular surgery and from cardiac infarction.

Generally, the amines (X) are used like the glucocorticoid pharmaceuticals for the treatment of the above human conditions as well as the animal conditions listed below. While the amines (X) are  
20 useful in both humans and animals in treating many of the same conditions and preventing damage from the same problems as the glucocorticoids, the amines (X) are useful in treating a number of conditions and preventing damage from conditions where the glucocorticoids are not useful. The amines (X) have no glucocorticoid  
25 activity and therefore, unlike the glucocorticoids, they can be given daily for long periods of time (used chronically) without the side effects associated with the glucocorticoids. This is a distinct advantage.

It is to be understood that each of the amines (X) is useful to  
30 a different degree for treating each of the conditions above. However, as is known to those skilled in the art, some of the amines (X) are better for treating some conditions and others are better for treating other conditions. In order to determine which compounds are better than others for a particular condition one can utilize  
35 known tests that do not require experimentation but only routine analysis.

For example, the fertile egg or chick embryo assay of Folkman, Nature 288, 551 (1980) or Science 221, 719 (1983), discloses an assay

-32-

to determine antiangiogenic activity which is indicative of inhibition of tumor growth and anti-cancer utility. Because of the ability of the compounds which are active in the Folkman embryo test to inhibit tumor growth, they are useful in the treatment of various diseases and conditions, especially various forms of cancer. Accordingly, they are administered to animals and humans to prolong survival or reduce pain and/or discomfort secondary to tumor growth and the like. Further, the arachidonic acid LD<sub>50</sub> test of Kohler, Thrombosis Res., 9, 67 (1976), identifies compounds which are antioxidants, which inhibit lipid peroxidation, and/or which inhibit the prostaglandin cascade and are useful in treating spinal trauma, mild and/or moderate to severe head injury, degenerative neurological disorders, etc. Another method useful for determining which particular compounds inhibit lipid peroxidation and which are therefore useful in treating spinal trauma, mild and/or moderate to severe head injury, degenerative neurological disorders, etc is described by Pryor in Methods of Enzymology 105, 293 (1984). Further, the mouse head injury assay of Hall, J. Neurosurg., 62, 882 (1980) discloses an assay from which one skilled in the art can readily determine which particular amines (VI) are useful in the acute treatment of spinal trauma or mild and/or moderate to severe head injury. Additionally, the cat 48 hr motor nerve degeneration model of Hall et al, Exp. Neurol., 79, 488 (1983) discloses a routine assay from which one skilled in the art can readily determine which particular amines (VI) are useful in treating chronic degenerative neurological disorders such as Parkinsonism, Alzheimer's disease etc. H. Johnson in Int. Arch. Allergy Appl. Immunol., 70, 169 (1983) has described the ascarias sensitized rhesus monkey assay for anti-asthma drugs.

The standard conditions for treatment are to give the amines (VI) orally or parenterally, e.g. IV (that is by injection, infusion or continuous drip) or IM, with a standard dose of about 0.05 to about 10 mg/kg/day IV or about 0.5 to about 50 mg/kg/day, one to four times daily by mouth.

For treating spinal trauma, mild and moderate to severe head injury, damage following cardiopulmonary resuscitation, cardiac infarction, organ damage during reperfusion after transplant, hemorrhagic, traumatic and septic shock, severe burns, ARDS, and nephrotic syndrome and preventing skin graft rejection, the standard conditions

-33-

are used. Typical treatment will involve an initial loading dose, e.g. an IV dose of 0.01 mg to 2 mg/kg followed by maintenance dosing e.g. IV infusion for a day to a week depending on the particular condition of the patient and the particular compound used. This may  
5 be supplemented with IM or oral dosing for days, weeks or months to prevent delayed neuronal degeneration in neurological applications (eg spinal trauma, head injury).

In treating subarachnoid hemorrhage and subsequent cerebral vasospasm or ischemic (thromboembolic) stroke the standard conditions  
10 are used and patients at risk are pre-treated orally.

In treating excess mucous secretion and asthma, the amines (X) are administered orally, IV and by inhalation in the standard dose. In treating excess mucous secretions the oral dose of the amines (X) used is from about 0.5 to about 50 mg/kg/day. The frequency of ad-  
15 ministration is one through 4 times daily. The oral administration of the amines (X) to treat excess mucous secretions may go on for months or even years. The susceptible individuals can be pre-treated a few hours before an expected problem. The IV dose is about 0.05 to about 20 mg/kg/day. The aerosol formulation contains about 0.05 to  
20 about 1.0% of the amines (X) and is administered or used about four times daily as needed.

In treating muscular dystrophy, Parkinsonism, Alzheimer's disease and other degenerative neurological disorders (amyotrophic lateral sclerosis; multiple sclerosis) amines (X) are administered  
25 orally using a dose of about 0.5 to about 50 mg/kg/day, administered or used one to four times a day. The treatment may go on for years.

In addition, utility in disorders or physiological phenomena dependent on angiogenesis or neovascularization such as embryo implantation (antifertility), arthritis, and atherosclerosis is  
30 exhibited with the amines (X) with or without co-administered oral heparin or systemic heparin fragments, see Science 221, 719 (1983).

In treating adriamycin-induced cardiac toxicity, the amines (X) are administered orally or IV using a dose of about 0.05 to about 50 mg/kg/day, preferably about 0.5 to about 10 mg/kg/day. The amines  
35 (X) are preferably given concomitantly with IV adriamycin or the individual is pre-treated with the amines (X).

For prophylaxis prior to and preventing damage after neurological or cardiovascular surgery the amines (X) are used according to

the standard conditions. The patient can be pretreated with a single IV or IM dose just prior to surgery or orally before and after surgery.

5 In treating osteo- or rheumatoid arthritis and other inflammatory diseases, the amines (X) are given orally or IM in doses of about 0.5 to about 50 mg/kg/day, one to four times daily. Orally the drug will be given over a period of months or years alone or with other steroidal or nonsteroidal antiinflammatory agents. The initial dose with some severe rheumatoid patients may be given IV and  
10 followed with an IV drip for up to 24 hr or more. In addition, intra-arterial administration may be employed.

In treating drug allergic reactions, the amines (X) are given in a dose of about 0.5 to 50 mg/kg/day, administered one to four times daily orally and IV. Typical treatment would be an initial IV  
15 loading dose followed by oral dosing for a few days or more.

In treating atherosclerosis and emphysema, the amines (X) are given orally in a dose of about 0.5 to about 50 mg/kg/day, one to four times daily for months or years.

20 In treating dermatological inflammatory conditions including psoriasis, the amines (X) are given orally in a dose of about 0.5 to about 50 mg/kg/day, one to four times daily or applied topically as a cream, ointment or lotion or equivalent dosage form in a concentration of about 0.05 to about 5% as long as needed. In treating these conditions the amines (X) can be used with steroidal agents.

25 The amines (X) are useful in the prevention and treatment of stress ulcers and of gastric intolerance caused by drugs such as non-steroidal anti-inflammatory compounds (NOSAC). Stress ulcers are ulcers that develop after exposure to severe conditions such as trauma, burns, sepsis, extensive surgery, acute illnesses, and the  
30 like. Patients in intensive care units are particularly prone to develop stress ulcers. Stress ulcers also include lesions that can lead to upper gastrointestinal bleeding; such bleeding is likely to be prevented by these compounds. NOSAC includes drugs such as ibuprofen, aspirin, indomethacin, naproxen, piroxicam and the like  
35 that are usually taken for analgesia, and that are often associated with gastrointestinal intolerance characterized by pain and lesions that may lead to bleeding. The amines (X) will be administered preferentially by the oral route either as tablets, capsules or

-35-

liquids, in doses ranging from about 5 to about 500 mg, two to four times a day. The treatment would be either preventive, i.e., starting before ulcers have formed in patients at risk of developing such lesions, or therapeutic, i.e., once the ulcers have formed. In patients whose clinical condition precludes swallowing the oral dosage forms, the amines (X) would be given either through a nasogastric tube, or parenterally, i.e., IV or IM. The parenteral doses would range from about 1 to about 100 mg and be administered one to four times a day or by IV.

10 In dogs, the amines (X) trauma, intervertebral diseases (slipped disk), traumatic shock, flea bite and other allergies.

In horses, the amines (X) are useful in treating endotoxic or septic shock which follows colic, pretreatment before surgery for colic and treatment of Founder (laminitis).

15 In cattle, the amines (X) are useful in treating acute coliform mastitis, bovine mastitis, acute allergic reaction to feed lot vaccination and shipping fever.

In pigs, the amines (X) are useful in treating porcine stress syndrome and thermal stress syndrome.

20 The term treatment or treating as used in this patent is used broadly and includes both treatment of an existing condition as well as preventing the same condition from occurring where such is possible as is well known to those skilled in the art. For example, the amines (X) can be used to treat existing asthma conditions and to prevent future ones from occurring. For example, the amines (X) treat spinal trauma and prevent rejection of skin grafts.

The amines (X) can be used with other pharmaceutical agents in treatment of the conditions listed above as is known to those skilled in the art.

30 The exact dosage and frequency of administration depends on the particular amines (X) used, the particular condition being treated, the severity of the condition being treated, the age, weight, general physical condition of the particular patient, other medication the individual may be taking as is well known to those skilled in the art and can be more accurately determined by measuring the blood level or concentration of the amines (X) in the patient's blood and/or the patients response to the particular condition being treated.

DEFINITIONS AND CONVENTIONS

The definitions and explanations below are for the terms as used throughout this entire document including both the specification and the claims.

5. I. CONVENTIONS FOR FORMULAS AND DEFINITIONS OF VARIABLES

- The chemical formulas representing various compounds or molecular fragments in the specification and claims may contain variable substituents in addition to expressly defined structural features. These variable substituents are identified by a letter or a letter followed by a numerical subscript, for example, "Z<sub>1</sub>" or "R<sub>i</sub>" where "i" is an integer. These variable substituents are either monovalent or bivalent, that is, they represent a group attached to the formula by one or two chemical bonds. For example, a group Z<sub>1</sub> would represent a bivalent variable if attached to the formula CH<sub>3</sub>-C(=Z<sub>1</sub>)H.
- 10 Groups R<sub>i</sub> and R<sub>j</sub> would represent monovalent variable substituents if attached to the formula CH<sub>3</sub>-CH<sub>2</sub>-C(R<sub>i</sub>)(R<sub>j</sub>)H<sub>2</sub>. When chemical formulas are drawn in a linear fashion, such as those above, variable substituents contained in parentheses are bonded to the atom immediately to the left of the variable substituent enclosed in parenthesis.
- 20 When two or more consecutive variable substituents are enclosed in parentheses, each of the consecutive variable substituents is bonded to the immediately preceding atom to the left which is not enclosed in parentheses. Thus, in the formula above, both R<sub>i</sub> and R<sub>j</sub> are bonded to the preceding carbon atom. Also, for any molecule with an established system of carbon atom numbering, such as steroids, these
- 25 carbon atoms are designated as C<sub>i</sub>, where "i" is the integer corresponding to the carbon atom number. For example, C<sub>6</sub> represents the 6 position or carbon atom number in the steroid nucleus as traditionally designated by those skilled in the art of steroid chemistry.
- 30 Likewise the term "R<sub>6</sub>" represents a variable substituent (either monovalent or bivalent) at the C<sub>6</sub> position.

Chemical formulas or portions thereof drawn in a linear fashion represent atoms in a linear chain. The symbol "-" in general represents a bond between two atoms in the chain. Thus CH<sub>3</sub>-O-CH<sub>2</sub>-CH(R<sub>1</sub>)-CH<sub>3</sub> represents a 2-substituted-1-methoxypropane compound. In a similar fashion, the symbol "=" represents a double bond, e.g., CH<sub>2</sub>=C(R<sub>1</sub>)-O-CH<sub>3</sub>, and the symbol "≡" represents a triple bond, e.g., HC≡C-CH(R<sub>1</sub>)-CH<sub>2</sub>-CH<sub>3</sub>. Carbonyl groups are represented in either one

-37-

of two ways:  $\text{-CO-}$  or  $\text{-C(=O)-}$ , with the former being preferred for simplicity.

Chemical formulas of cyclic (ring) compounds or molecular fragments can be represented in a linear fashion. Thus, the compound  
 5 4-chloro-2-methylpyridine can be represented in linear fashion by  
 $\text{N}^*=\text{C}(\text{CH}_3)\text{-CH=CCl-CH-C}^*\text{H}$  with the convention that the atoms marked  
 with an asterisk (\*) are bonded to each other resulting in the  
 formation of a ring. Likewise, the cyclic molecular fragment, 4-  
 (ethyl)-1-piperazinyI can be represented by  $\text{-N}^*-(\text{CH}_2)_2\text{-N}(\text{C}_2\text{H}_5)\text{-CH}_2\text{-}$   
 10  $\text{C}^*\text{H}_2$ .

A cyclic (ring) structure for any compound herein defines an orientation with respect to the plane of the ring for substituents attached to each carbon atom of the cyclic compound. In formulas depicting such compounds, a substituent attached to a carbon atom  
 15 below the plane of the ring is identified as being in the alpha ( $\alpha$ ) configuration and is indicated by a broken, dashed or dotted line attachment to the carbon atom, i.e., by the symbol  $\text{-} \cdot \cdot \cdot \text{-}$  or  $\text{-} \cdot \cdot \cdot \text{-}$ . The corresponding substituent attached above the plane of the ring is identified as being in the beta ( $\beta$ ) configuration. When  
 20 a variable substituent is bivalent, the valences may be taken together or separately or both in the definition of the variable. For example, a variable  $\text{R}_i$  attached to a carbon atom as  $\text{-C(=R}_i\text{)-}$  might be bivalent and be defined as oxo or keto (thus forming a carbonyl group  $\text{-CO-}$ ) or as two separately attached monovalent  
 25 variable substituents  $\alpha\text{-R}_{i-j}$  and  $\beta\text{-R}_{i-k}$ . When a bivalent variable,  $\text{R}_i$ , is defined to consist of two monovalent variable substituents, the convention used to define the bivalent variable is of the form  $\alpha\text{-R}_{i-j}:\beta\text{-R}_{i-k}$  or some variant thereof. In such a case both  $\alpha\text{-R}_{i-j}$  and  $\beta\text{-R}_{i-k}$  are attached to the carbon atom to yield  $\text{-C}(\alpha\text{-R}_{i-j})$   
 30  $(\beta\text{-R}_{i-k})\text{-}$ . For example, when the bivalent variable  $\text{R}_6$ ,  $\text{-C(=R}_6\text{)-}$  is defined to consist of two monovalent variable substituents, two monovalent variable substituents are  $\alpha\text{-R}_{6-1}:\beta\text{-R}_{6-2}$ , ....  $\alpha\text{-R}_{6-9}:\beta\text{-R}_{6-10}$ , etc, yielding  $\text{-C}(\alpha\text{-R}_{6-1})(\beta\text{-R}_{6-2})\text{-}$ , ....  $\text{-C}(\alpha\text{-R}_{6-9})(\beta\text{-R}_{6-10})\text{-}$ , etc. Likewise, for the bivalent variable  $\text{R}_{11}$ ,  $\text{-C(=R}_{11}\text{)-}$ , two  
 35 monovalent variable substituents are  $\alpha\text{-R}_{11-1}:\beta\text{-R}_{11-2}$ . For a ring substituent for which separate  $\alpha$  and  $\beta$  orientations do not exist (e.g. due to the presence of a carbon carbon double bond in the ring), and for a substituent bonded to a carbon atom which is not

part of a ring the above convention is still used, but the  $\alpha$  and  $\beta$  designations are omitted.

Just as a bivalent variable may be defined as two separate monovalent variable substituents, two separate monovalent variable substituents may be defined to be taken together to form a bivalent variable. For example, in the formula  $-C_1(R_i)H-C_2(R_j)H-$  ( $C_1$  and  $C_2$  define arbitrarily a first and second carbon atom, respectively)  $R_i$  and  $R_j$  may be defined to be taken together to form (1) a second bond between  $C_1$  and  $C_2$  or (2) a bivalent group such as oxa ( $-O-$ ) and the formula thereby describes an epoxide. When  $R_i$  and  $R_j$  are taken together to form a more complex entity, such as the group  $-X-Y-$ , then the orientation of the entity is such that  $C_1$  in the above formula is bonded to X and  $C_2$  is bonded to Y. Thus, by convention the designation "...  $R_i$  and  $R_j$  are taken together to form  $-CH_2-CH_2-O-CO-$  ..." means a lactone in which the carbonyl is bonded to  $C_2$ . However, when designated "...  $R_j$  and  $R_i$  are taken together to form  $-CH_2-CH_2-O-CO-$  the convention means a lactone in which the carbonyl is bonded to  $C_1$ .

The carbon atom content of variable substituents is indicated in one of two ways. The first method uses a prefix to the entire name of the variable such as " $C_1-C_4$ ", where both "1" and "4" are integers representing the minimum and maximum number of carbon atoms in the variable. The prefix is separated from the variable by a space. For example, " $C_1-C_4$  alkyl" represents alkyl of 1 through 4 carbon atoms, (including isomeric forms thereof unless an express indication to the contrary is given). Whenever this single prefix is given, the prefix indicates the entire carbon atom content of the variable being defined. Thus  $C_2-C_4$  alkoxycarbonyl describes a group  $CH_3-(CH_2)_n-O-CO-$  where n is zero, one or 2. By the second method the carbon atom content of only each portion of the definition is indicated separately by enclosing the " $C_i-C_j$ " designation in parentheses and placing it immediately (no intervening space) before the portion of the definition being defined. By this optional convention  $(C_1-C_3)$ alkoxy-carbonyl has the same meaning as  $C_2-C_4$  alkoxycarbonyl because the " $C_1-C_3$ " refers only to the carbon atom content of the alkoxy group. Similarly while both  $C_2-C_6$  alkoxyalkyl and  $(C_1-C_3)$ alkoxy $(C_1-C_3)$ alkyl define alkoxyalkyl groups containing from 2 to 6 carbon atoms, the two definitions differ since the former definition allows either the alkoxy or alkyl portion alone to contain 4 or 5 carbon atoms while

-39-

the latter definition limits either of these groups to 3 carbon atoms.
